Shifts in the size of fish from a culturally important recreational fishery

Mark Scheuerell

22 October 2020

Data

The original Tengu Derby data were provided to me by Tom Quinn on 16 June 2020 in the form of an MS Excel file titled Tengu_derby_leaders through 2019 derby.xls. I exported one worksheet of interest (data in kg) as ~/data/tengu_derby_data.csv. The same Excel file also included a worksheet with information from WDFW on the number of natural- and hatchery-origin Chinook, and the mean mass of Chinook (Losee Chiook data), which I exported as ~/data/wdfw_data.csv

```
## set data dir
datadir <- here::here("data")</pre>
## import raw Tengu data
tengu_data <- readr::read_csv(file.path(datadir, "tengu_derby_data.csv"))</pre>
## Parsed with column specification:
## cols(
     derby = col_double(),
##
##
     year = col_double(),
##
     month = col_character(),
     days = col_double(),
##
##
     members = col_double(),
##
     total_catch = col_double(),
     n over 10 = col double(),
##
##
     n_over_5 = col_double(),
     size_1 = col_double(),
##
##
     size_2 = col_double(),
     size_3 = col_double(),
##
     size_4 = col_double(),
##
##
     size_5 = col_double()
## )
## import raw WDFW data
wdfw_data <- readr::read_csv(file.path(datadir, "wdfw_data.csv"))</pre>
## Parsed with column specification:
## cols(
##
     year = col_double(),
```

```
## NOR = col_double(),
## HOR = col_double(),
## total = col_double(),
## size = col_double()
```

Fishing effort

The Tengu Derby dataset lacks the necessary detail to calculate a proper index of the catch per unit effort (CPUE) because effort is ill-defined. That is, although we know the total number of days per year the derby was open and the total number of anglers that participated per year, we don't know how many days *each* angler fished. Therefore, we assumed that each angler fished every day the derby was open, which is almost certainly an overestimate of the true effort, but we have no reason to believe there would be any systematic change over time.

```
## CPUE
cpue <- (tengu_data$total_catch / (tengu_data$days * tengu_data$members))[-c(1:5)]</pre>
```

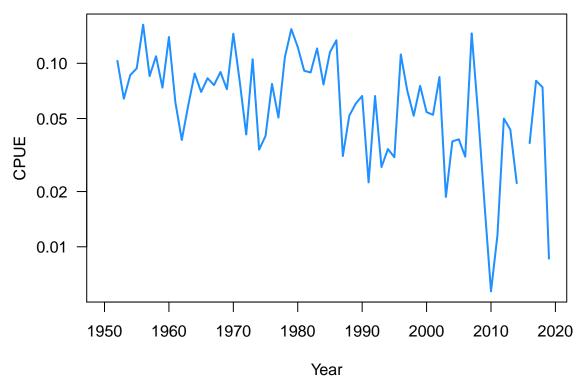

Figure 1. Time series of catch per unit effort of blackmouth from the Tengu Derby. Note that the y-axis is on a natural log scale.

Changes in catch over time

We can model CPUE data with a state-space model, such that the observed CPUE are treated as an index of the general abundance of blackmouth within this region of Puget Sound. Because the CPUE appears to generally decline over time, I fit two different state models:

- 1) a normal random walk; and
- 2) a biased random walk.

Because CPUE is necessarily bounded by zero at a minimum, I fit models to the log-transformed CPUE. Specifically, the models are defined as

$$c_t = x_t + v_t \tag{1}$$

and

$$x_t = x_{t-1} + u + w_t (2)$$

or

$$x_t = x_{t-1} + w_t \tag{3}$$

where c_t is the log_e-transformed CPUE, x_t is the true, but unobserved abundance of blackmouth, u is a bias term, and $v_t \sim N(0, \sigma_u)$ and $w_t \sim N(0, \sigma_c)$.

```
## model setup
mod_list <- list(
    B = matrix(1),
    U = matrix("u"),
    Q = matrix("q"),
    Z = matrix(1),
    A = matrix(0),
    R = matrix("r")
)

## log the response
l_cpue <- matrix(log(cpue), nrow = 1)</pre>
```

Fit biased random walk

```
## fit biased RW (Eqn 2)
cpue_brw <- MARSS(l_cpue, model = mod_list)
## Success! abstol and log-log tests passed at 435 iterations.
## Alert: conv.test.slope.tol is 0.5.
## Test with smaller values (<0.1) to ensure convergence.
##
## MARSS fit is</pre>
```

```
## Estimation method: kem
## Convergence test: conv.test.slope.tol = 0.5, abstol = 0.001
## Estimation converged in 435 iterations.
## Log-likelihood: -58.58509
## AIC: 125.1702
                   AICc: 125.8051
##
##
         Estimate
## R.r
           0.3280
## U.u
          -0.0184
## Q.q
           0.0000
## x0.x0 -2.0836
## Initial states (x0) defined at t=0
##
## Standard errors have not been calculated.
## Use MARSSparamCIs to compute CIs and bias estimates.
## 95% CI for bias
cpue_brw <- MARSSparamCIs(cpue_brw)</pre>
Fit unbiased random walk
## fit unbiased RW (Eqn 3)
mod_list$U <- matrix(0)</pre>
cpue_rw <- MARSS(l_cpue, model = mod_list)</pre>
## Success! abstol and log-log tests passed at 106 iterations.
## Alert: conv.test.slope.tol is 0.5.

##

R.r

Q.q

```
## x0.x0 -2.36803
## Initial states (x0) defined at t=0
##
## Standard errors have not been calculated.
## Use MARSSparamCIs to compute CIs and bias estimates.
```

The 95% confidence interval for the bias term (u) is (-0.03, -0.01), and the model with a bias term has an AICc value ~5.6 units lower than the model without a bias term, suggesting there is indeed

some data support for a systematic downward trend in the log-transformed CPUE over time.

Model fit to CPUE

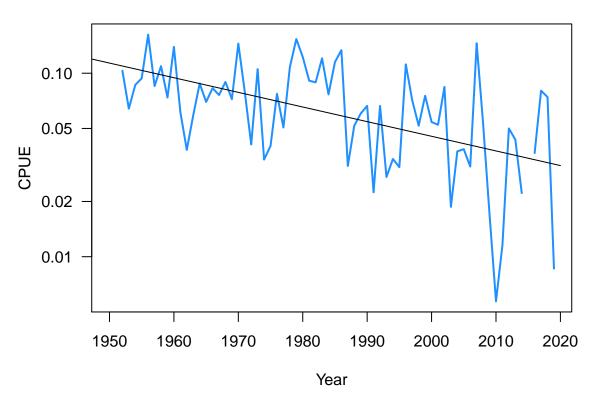

Figure 2. Time series of observed CPUE (blue) and the fit for the biased random walk model (Eqn 2; black).

Changes in fish size over time

The data set contains three different indicators of fish size over time:

- 1) the total number of fish over 10 pounds (~ 4.55 kg);
- 2) the total number of fish over 5 pounds (~2.27 kg); and
- 3) the masses (kg) of the 5 largest fish.

Clearly (1) and (2) will be correlated, as (1) is a subset of (2). Furthermore, the probability of catching a fish greater than 5 or 10 pounds clearly increases as the total number of fish caught also increases. Thus, I modeled the proportion of fish caught in a given year that were greater than the 2 size thresholds.

```
## proportion of fish >10 lbs
p10 <- tengu_data$n_over_10 / tengu_data$total_catch</pre>
```

```
## screen for p = 0 & change to p = 0.001
p10[p10 == 0] <- 0.001

## proportion of fish >5 lbs
p5 <- tengu_data$n_over_5 / tengu_data$total_catch
## screen for p = 1 & change to p = 0.999
p5[p5 == 1] <- 0.999

## combine proportional data
fish_sizes <- cbind("Prop. over 10 lbs" = p10, "Prop. over 5 lbs" = p5) %>%
ts(start = min(tengu_data$year))
```

Here are plots of the three size metrics over time.

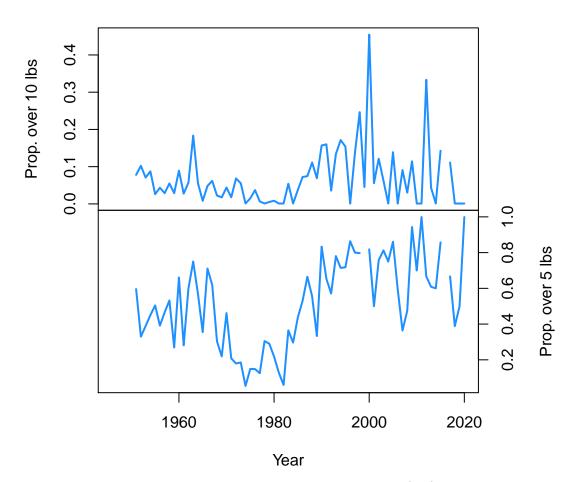

Figure 3. Time series of the proportion of fish over 10 pounds (top) and over 5 pounds (bottom).

There appears to be an overall decline in fish size from the mid 1940s until the early 1980s, when fish sizes increased rapidly before declining again until present.

Fit biased random walk

Just as I did with the CPUE data, I fit both biased and unbiased forms of random walk models to the fish size data, with the response being the logit-transformed proportions of fish over 10 and 5 pounds.

```
## response for fish >10 lbs
l_size_10 <- matrix(qlogis(p10), nrow = 1)</pre>
## response for fish >5 lbs
l_size_5 <- matrix(qlogis(p5), nrow = 1)</pre>
## model setup
mod list <- list(</pre>
 B = matrix(1),
 U = matrix("u"),
  Q = matrix("q"),

```

For the model based upon the proportion of fish over 10 pounds, the 95% confidence interval for the bias term (u) is (-0.132, 0.052), and the model with a bias term has an AIC value that is only ~ 1.5 units lower than the model without a bias term, suggesting there is essentially no data support for a systematic downward trend in the log-transformed size over time. This is not much of a surprise, however, given the apparent temporal patterns in the data.

For the model based upon the proportion of fish over 5 pounds, the 95% confidence interval for the bias term (u) is (-0.035, 0.106), and the model with a bias term has an AIC value that is only ~ 1.3 units lower than the model without a bias term, suggesting there is essentially no data support for a systematic downward trend in the log-transformed size over time.

Model fit to size data

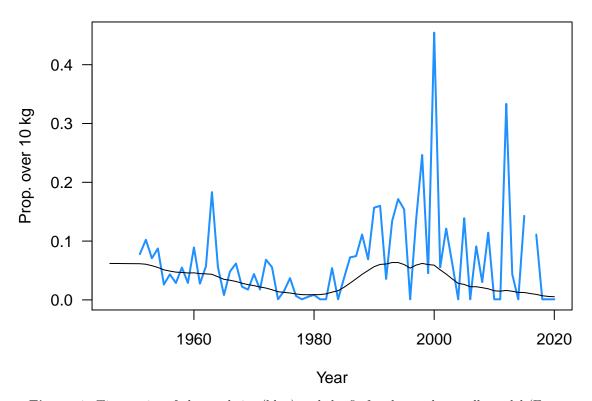

Figure 4. Time series of observed size (blue) and the fit for the random walk model (Eqn 3; black).

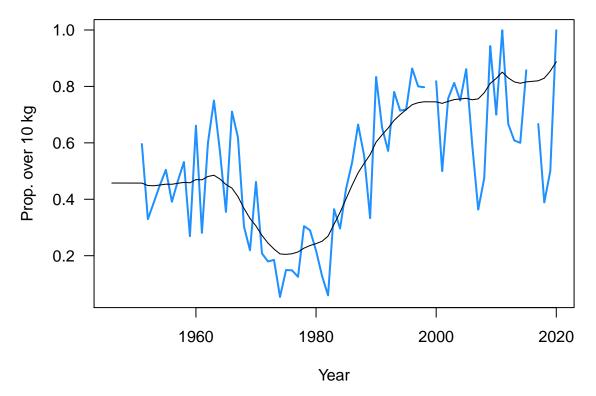

Figure 5. Time series of observed size (blue) and the fit for the random walk model (Eqn 3; black).

Comparisons between the Tengu Derby & WDFW

Although the two data sources come from different times, places, and gear types, they both contain information on the temporal changes in size and CPUE over time. I investigated whether or not the temporal trends in the two data sources track one another (i.e., are representative of one "state of nature"). To do so, I used a multivariate state-space model of the general form

$$\mathbf{y}_t = \mathbf{Z}\mathbf{x}_t + \mathbf{a} + \mathbf{v}_t \tag{4}$$

$$\mathbf{x}_t = \mathbf{x}_{t-1} + \mathbf{w}_t \tag{5}$$

For both forms of the model, \mathbf{y}_t is a $[2 \times 1]$ vector of the observed data from both sources, \mathbf{a} is a $[2 \times 1]$ vector of offsets (intercepts), and $\mathbf{v}_t \sim \text{MVN}(\mathbf{0}, \mathbf{R})$. For both models, I assumed that the observation errors at time t (\mathbf{v}_t) are independent and differently distributed, such that

$$\mathbf{R} = \begin{bmatrix} r_1 & 0 \\ 0 & r_2 \end{bmatrix}$$

Fish size

The time series from WDFW begins in 1970 and runs through 2015, but the Tengy Derby data is missing size information for 2015, so I restricted my analysis to the 45 years from 1970-2014. Again I fit models to the log-transformed size data.

One pattern over time

For the model with only one state of nature, **Z** is a $[2 \times 1]$ vector of 1's, \mathbf{x}_t is a $[1 \times 1]$ scalar of the true state, and $\mathbf{w}_t \sim \mathrm{N}(0,q)$, such that

$$\begin{bmatrix} y_{\text{Tengu}} \\ y_{\text{WDFW}} \end{bmatrix}_t = \begin{bmatrix} 1 \\ 1 \end{bmatrix} x_t + \begin{bmatrix} a_{\text{Tengu}} \\ a_{\text{WDFW}} \end{bmatrix} + \begin{bmatrix} v_{\text{Tengu}} \\ v_{\text{WDFW}} \end{bmatrix}_t$$

$$x_t = x_{t-1} + w_t$$

(8)

(9)

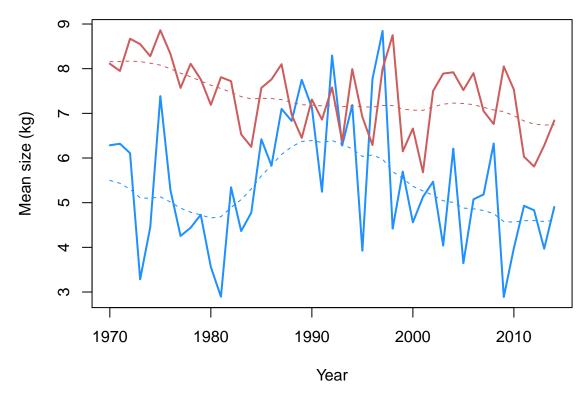

Figure 6. Time series of observed fish size from the Tengu derby (blue) and WDFW surveys (red), including fits from the multivariate random walk model (Eqns 8 & 9; dashed).

Summary of size comparison

The model with one common state has an AICc value of -50.4 and the model with two unique states has an AICc value of -49.1, which indicates rather modest support for two unique temporal patterns in the data.

CPUE

The time series of CPUE from WDFW begins in 1968 and runs through 2015, but the Tengy Derby data is missing catch information for 2015, so I restricted my analysis to the 47 years from 1968-2014. Because the units for the catch data differ for the two datasets and vary by several orders of magnitude, I log-transformed each of the time series and then normalized them to have mean zero and unit variance.

One pattern over time

Here is the model for one common temporal trend, analogous to Equations 6 & 7 above.

```
## standardize the mean and variance

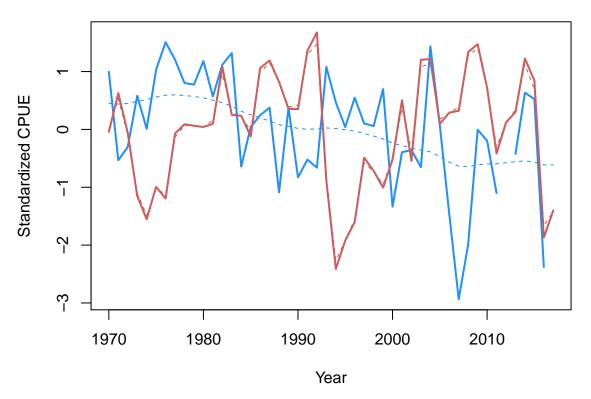

Figure 8. Time series of observed fish CPUE from the Tengu derby (blue) and WDFW surveys (red), including fits from the multivariate random walk model (Eqns 8 & 9; dashed).

Summary of CPUE comparison

The model with one common state has an AICc value of 277.9 and the model with two unique states has an AICc value of 266, which provides reasonable support for two unique temporal patterns in the data.
